Relations

- Restaurant(name, owner, capacity, country)
- Patron(PID, fname, lname, birthday)
- Dish(DID, name, dietary)
- Reservation(RID, PID, rname, date)
- Order(RID, DID, number)
- Rating(PID, rname, rating)

Part 1

1. Question: Report the name of the Patron that has given the highest rating to a restaurant. If there are ties, report all of them.

Let $r1$ and $r2$ be two Rating relations

$$r1 := \rho \text{ r1 Rating} \quad (1)$$

$$r2 := \rho \text{ r2 Rating} \quad (2)$$

Let $nottop$ be the relation of all PID's that are not the maximum

$$nottop(PID) := \Pi_{(r1.PID)} (\sigma_{r2.rating > r1.rating \wedge r2.PID \neq r1.PID} (r1 \times r2)) \quad (3)$$

Let $temp$ be the relation of all maximums, pid's that are in Rating but not in $nottop$. Natural Join $temp$ with $patron$ to get the names of the Patrons with pids in $temp$.

$$temp(PID) := (\Pi_{PID} Rating) - nottop \quad (4)$$

$$\Pi_{fname, lname} (temp \bowtie Patron) \quad (5)$$

2. Question: Report the name of the restaurant for which the highest number of reservations were made. If there are ties report all of them.

Can't be done with relational algebra operations.

3. Question: Report the PID(s) of the Patrons(s) who reserved a spot at a restaurant, but did not order anything.

Make an *pidsOrdered* relation that holds the pid of every patron who has made an order by natural joining *Order* with *Reservation*. Then subtract *pidsOrdered* from the set of all *Reservation* pids, this will give all the patron pids who have a reservation but have not ordered anything.

$$pidsOrdered(RID) := \Pi_{RID} (Order \bowtie Reservation) \quad (6)$$

$$(\Pi_{PID} Reservation) - pidsOrdered \quad (7)$$

4. Question: Report the name(s) of the Patrons(s) who have made a reservation to the restaurant named 'Boston Pizza' and ordered 3 of a dish called 'Margherita Pizza'.

Make a relation called *pBP* that holds the pid and rid of every patron who has made a reservation at 'Boston Pizza'. And a relation called *mp* that holds the did of a dish called 'Margherita Pizza'.

$$pBP(PID, RID) := \Pi_{PID, RID} (\sigma_{rname='Boston Pizza'}(Reservation)) \quad (8)$$

$$mp(DID) := \Pi_{DID} (\sigma_{name='Margherita Pizza'}(Dish)) \quad (9)$$

Let *temp* be the relation holding every order from Boston pizza that has 3 of any dish. Then, natural join *temp* and *mp* to get all the orders where 'Margherita Pizza' was ordered 3 times. And natural join again with *Patron* to get the names of the patrons.

$$temp := \sigma_{number=3}(pBP \bowtie Order) \quad (10)$$

$$\Pi_{fname, lname}[(\Pi_{PID}(mp \bowtie temp)) \bowtie Patron] \quad (11)$$

5. Question: Report the owner of the restaurant with the highest average rating. If there are ties, report all of them.

We can't find average in relational algebra.

Let *r1* and *r2* be two instances of *Rating* relation.

$$r1 := \rho \text{ r1 Rating} \quad (12)$$

$$r2 := \rho \text{ r2 Rating} \quad (13)$$

...

6. Question: Report the capacities of the restaurants from which patrons have so far only ordered foods with a 'gluten-free' dietary restriction.

Make a relation called *glutenfree* that holds the did, of every dish that is gluten free. And make a relation called *gfOrders* that holds the rid of every patron who has ordered a gluten free patron.

$$glutenfree(DID) := \Pi_{RID}(\sigma_{directory='gluten-free'}(Dish)) \quad (14)$$

$$temp(RID) := \Pi_{RID}(glutenfree \bowtie Order) \quad (15)$$

Make another relation called *restnames* that holds the restaurant name of every restaurant that serves 'gluten-free food'. Do this by natural joining *temp* with *Reservation*. Finally cross *restnames* and *Restaurant* to get the capacity of every restaurant serving 'gluten-free'.

$$restnames(rname) := \Pi_{rname}(temp \bowtie Reservation) \quad (16)$$

$$\Pi_{capacity}(\sigma_{restnames.rname=Restaurant.name}(restnames \times Restaurant)) \quad (17)$$

7. Question: Report the restaurant owner for which the very earliest reservation out of all the reservations in the database was made. Report any ties.

Make two relations, *r1*, *r2* both copies of *Reservation*.

$$r1 := \rho \text{ } r1 \text{ } Reservation \quad (18)$$

$$r2 := \rho \text{ } r2 \text{ } Reservation \quad (19)$$

Next create 3 relations, *notbottom*, *bottom*, and *restname*.

'notbottom' is the rid of every reservation where there exists some other date in *Reservation* that is smaller than the current rid date.

'bottom' is the set of smallest (earliest) dates, if there are multiple dates tied there will be multiple rid's.

'restname' is a set of restaurant names that the rid's in the bottom relation visit.

$$notbottom(RID) := \Pi_{r2.RID} (\sigma_{r1.date < r2.date \wedge r1.RID \neq r2.RID}(r1 \times r2)) \quad (20)$$

$$bottom(RID) := (\Pi_{RID} Reservation) - notbottom \quad (21)$$

$$restname(rname) := \Pi_{rname} (bottom \bowtie Restaurant) \quad (22)$$

Finally project the owner of the restaurants where earliest reservations were made.

8. Question: Report the PID(s) of the Patrons who have made reservations to the restaurant named 'Red Lobster' on their birthday.

Make a relation called *RLpid* which holds the pid and date of every reservation made to 'Red Lobster'.

Natural join *RLpid* with *Patron*, and select every row where date = birthday, and project out the pid.

$$RLpid(PID, date) := \Pi_{PID, date} (\sigma_{rname='RedLobster'} Reservation) \quad (23)$$

$$\Pi_{PID} (\sigma_{date=birthday}(RLpid \bowtie Patron)) \quad (24)$$

9. Question: Consider all patrons that have made reservations to at least two different restaurants. For each of those patrons, report their name, and the names and ratings of all of the restaurants they went to (not ones they rated without actually going to).

Make two relations *p1* and *p2*, both copies of *Reservation*.

$$p1 := \rho \text{ } p1 \text{ } Reservation \quad (25)$$

$$p2 := \rho \text{ } p2 \text{ } Reservation \quad (26)$$

Next make 3 relations, 'atleast2res', 'names', and 'pidrate'.

'atleast2res' holds the pid and restaurant name of every patron who have made reservations to at least two different restaurants.

'names' holds the pid, and names of every patron in 'atleast2res'.

'pidrate' holds the pid, restaurant name, and rating given by every patron in 'atleast2res'.

$$atleast2res(PID, rname) := \rho \text{ atleast2res } (\Pi_{p1.PID, p1.rname} [\sigma(pl.PID = p2.PID \quad (27)$$

$$\wedge p1.RID \neq p2.RID \quad (28)$$

$$\wedge p1.rname \neq p2.rname)(r1 \times r2)]) \quad (29)$$

the $\rho \text{ atleast2res}$ at the beginning of the statement is to clarify that all the columns belong to 'atleast2res', and they will be referred to by atleast2res.PID not p1.PID, this adjustment was needed in Relax, added just in case. 'pidrate' and 'names' also includes this precaution.

$$names(PID, fname, lname) := \rho \text{ names } (\Pi_{p1.PID, p1.rname} [\sigma_{a.PID=pt.PID} (\rho \text{ a atleast2res} \times \rho \text{ pt Patron})] \quad (30)$$

In 'pidrate' we cross 'atleast2res' and Rating, and select for every element in 'atleast2res' so we can get the rating given only if the patron has been to the restaurant. In the query I assign a to be 'atleast2res' and 'rat' to be Rating to make it shorter.

$$pidrate(PID, rname, rating) := \rho \text{ pidrate } (\Pi(a.PID, rat.rname, rat.rating) \quad (31)$$

$$[\sigma(a.PID = rat.PID \quad (32)$$

$$\wedge a.rname = rat.name) \quad (33)$$

$$(\rho \text{ a atleast2res} \times \rho \text{ rat Rating})] \quad (34)$$

Finally cross pidrate, and names and project patron names, restaurant names, and restaurant ratings as required.

$$\Pi_{(n.fname, n.lname, p.rname, p.rating) \quad (35)$$

$$[\sigma_{n.PID=p.PID} (\rho \text{ p pidrate} \times \rho \text{ n names})] \quad (36)$$

Part 2: Integrity constraints

1. Question: A restaurant owner can only own one restaurant.

Let $r1$ and $r2$ be two Restaurant relations

$$r1 := \rho \text{ r1 Restaurant} \quad (37)$$

$$r2 := \rho \text{ r2 Restaurant} \quad (38)$$

A restaurant owner can only own one restaurant is the same as saying a restaurant owner cannot own more than 1 restaurant.

$$\sigma_{r1.owner=r2.owner \wedge r2.name \neq r1.name} (r1 \times r2) = \emptyset \quad (39)$$

2. Question: Patrons who did not make a reservation for a restaurant cannot review it.

Let res be a Reservation relation, and rat be a Rating relation

$$res := \rho \text{ res Reservation} \quad (40)$$

$$rat := \rho \text{ rat Rating} \quad (41)$$

Get every patron id who rated a restaurant along with the restaurant they rated and store that in temp. Check if there exists a pid, restaurant combination that does not exist in reservation, set to null.

$$temp(PID, rname) := \Pi_{PID, rname} rat \quad (42)$$

$$temp - (\sigma_{PID, rname} Reservation) = \emptyset \quad (43)$$

3. Question: A Patron cannot make multiple reservations in one day for a restaurant that has a capacity less than 100.

Let $res1$ and $res2$ be two Reservation relations

$$res1 := \rho \text{ res1 Reservation} \quad (44)$$

$$res2 := \rho \text{ res2 Reservation} \quad (45)$$

Make a relation 'temp', that holds the pid and rname of every row tuple where the patron has two reservations for the same restaurant on the same day.

$$temp(PID, name) := \Pi_{res1.PID, res1.rname} \quad (46)$$

$$(\sigma(res1.PID = res2.PID \quad (47)$$

$$\wedge res1.rname = res2.rname \quad (48)$$

$$\wedge res1.RID \neq res2.RID \quad (49)$$

$$\wedge res1.date = res2.date)(res1 \times res2)) \quad (50)$$

Natural join temp with Restaurant over name (restaurant name), and get which restaurants have less than 100 capacity.

$$rest := \rho \text{ rest Restaurant} \quad (51)$$

$$\sigma_{rest.capacity < 100}(rest \bowtie temp) = \emptyset \quad (52)$$
